II. c. 22 introduced it in the common-law courts, and its provisions have been generally reënacted in the United States. In most jurisdictions, as at common law, set-off can be had only on a liquidated claim between the same parties in the same capacities, and must be pleaded and answered with the same formality as in an independent action. A set-off may give rise to a judgment in favor of the original defendant. In the common law the debts do not extinguish each other until judgment is had to that effect, but in the civil-law systems generally, as the French and Roman Dutch, the opposing debts extinguish each other ratably by operation of law. *Set-off* differs from *recoupment*, as the latter generally grows out of the same matter or contract with the plaintiff's claim. sex (sĕks). Obs. or dial. Eng.

or of pertaining to the distinctive function of the male or female in reproduction. *Conjugation*, or *fertilization* (union of germ plasm of two individuals), a process evidently of great but not readily explainable importance in the perpetuation of most organisms, seems to be the purpose of differentiation of sex, which occurs in nearly all organisms at least at some stage in their life history. Sex is manifested in the conjugating cells by the larger size, abundant food material, and immobility of the female cell (*egg, egg cell*, or *ovum*), and the small size and locomotive power of the male cell (*spermatozoön* or *spermatozoid*), and in the adult organisms often by many structural, physiological, and (in higher forms) psychological characters, aside from the necessary modification of the reproductive apparatus. Cf. HERMAPHRODITE, 1. In botany, by a false analogy, the term *sex* is often extended to the distinguishing peculiarities of staminate and pistillate flowers, and hence in dioecious plants to the individuals bearing them.

☞ In certain insects and other arthropods the body and germ cells have been shown to contain sometimes one or more chromosomes of a special kind (called **idiochromosomes**) in addition to the ordinary chromosomes, and these have a relation to sex. In the simplest and most typical cases, two kinds of spermatozoa are produced, differing in having or not having one idiochromosome, which in such cases is commonly called **accessory chromosome**, **heterotropic chromosome**, *or* **monosome**. A spermatozoön having the accessory chromosome produces (on fertilizing an egg) a female, a spermatozoön lacking it produces a male.

2. One of the two divisions of organisms formed on the distinction of male and female; males or females collectively.

shall (shăl), *v. t. & auxiliary; pres., sing.* 1st & 3d pers. SHALL, 2d SHALT, *pl.* SHALL; *pret.* SHOULD. Infinitive and participles lacking. [ME. *shal, schal,* pret. *sholde, scholde,* AS. *scal, sceal,* I am obliged (orig. a pret. ind.), pret. *scolde, sceolde,* inf. *sculan;* akin to OS. *skulan,* pres. *skal,* pret. *skolda,* D. *zullen,* pres. *zal,* pret. *zoude, zou,* OHG. *solan, scolan,* pres. *scal, sol,* pret. *scolta, solta,* G. *sollen,* pres. *soll,* pret. *sollte,* Icel. *skulu,* pres. *skal,* pret. *skyldi,* Sw. *skola,* pres. *skall,* pret. *skulle,* Dan. *skulle,* pres. *skal,* pret. *skulde,* Goth. *skulan,* pres. *skal,* pret. *skulda,* and to AS. *scyld* guilt, G. *schuld* guilt, fault, debt.] **1.** [*v. t.*] Owe; be under obligation for. *Obs.* "By the faith I *shall* to God." *Court of Love.*
2. [*auxil.*, followed by the infinitive without *to.*] Am (is, are, etc.) obliged; must. Hence, am (is, are, etc.) to; — forming future-tense phrases. See also SHOULD. *Shall* and *will* are both used as future auxiliaries, the choice between them arising from their respective special implications of necessity and intention. Thus *shall,* when used in the 2d or 3d person, has a special force from the fact that the speaker predicts or promises some one else's action, and hence is expressive of some authority or compulsion on the speaker's part; as in, you *shall* go; thou *shalt* not kill; he *shall* rue it. In the 1st person *shall* has no special force, since one can predict or promise his own future action as a matter of course. Hence *shall* is here weakened into expressing mere futurity, as in, I *shall* be glad to see you; we *shall* go, although by emphasis or context its futurity may take on the weightier sense of necessitation or destiny; as in, I *shall* suffer; we *shall* see. *Will,* on the other hand, when used in the 1st person, has its primary force of *volition* or *willingness;* as in, I *will* go; that is, I am willing, or, emphatically, I am determined, to go. In the 2d and 3d person the idea of volition is weakened or lost, the speaker not readily being thought of as asserting an intention in another's mind. Hence in you *will* go, they *will* go, *will* denotes simple futurity, though again the futurity may be emphasized as certain. The forms for expressing simple futurity are thus: I (we) *shall;* you (he, etc.) *will;* those for implying volition, authority, or compulsion in the speaker are: I (we) *will;* you (he, etc.) *shall.* In a question the form is used that is expected in the answer; thus, will I? *shall* he? *will* he? *shall* you? is of course rarely proper, as implying that the questioner asks for his own intention. The context and the expressive intention of the writer may, of course, often set aside the application of the rules here given. Thus *shall* is used for simple futurity in all persons: (1) after conditionals, as in, whether I (you, he) *shall* go; (2) in such clauses of indirect discourse as, you think you *shall* go; he says he *shall* go; (3) in such questions as, how *shall* he cut without any knife? the context here excluding the implication that the speaker asserts authority or necessity. In commands, also, *will* is often used by way of courtesy; as in, you *will* report to the colonel.
☞ *Shall* and *will, should* and *would,* are often misused, as in the following examples: —
I am able to devote as much time and attention to other subjects as I *will* [shall] be under the necessity of doing next winter. *Chalmers.*
A countryman, telling us what he had seen, remarked that if the conflagration went on, as it was doing, we *would* [should] have . . . the Old Town of Edinburgh to rebuild. *H. Miller.*
I feel assured that I *will* [shall] not have the misfortune to find conflicting views held by one so enlightened as . . . *J. F. Hodson.*
☞ *Shall* and *will* may be used elliptically for *shall* or *will* go. "*I'll* to her lodgings." *Marlowe.*
He to England *shall* along with you. *Shak.*

The sharks are mostly marine and, though widely distributed, most abundant in warm seas. They are usually of medium or large size, the largest existing fishes (30 to 40 feet long) being of this group. Still larger extinct sharks are known. Sharks have a tough, usually dull gray, sometimes conspicuously spotted, skin, which is roughened by minute tubercles. The tail is strongly heterocercal and the snout is produced beyond the mouth, which generally has formidable teeth. Though some feed chiefly on shellfish, most are very active, voracious, and destructive of other fishes, and the larger ones are often dangerous to man. Their flesh is coarse. Oil is obtained from the liver of many species. Among the more important kinds are the basking, blue, hammerhead, man-eating, and porbeagle sharks, and the dogfishes. Syn. — Piercing, penetrating; pungent, poignant, acid, tart, acrid, harsh; biting, bitter, acrimonious, sarcastic, caustic; fierce, ardent, fiery; shrewd, sagacious, astute. — SHARP, KEEN, ACUTE, CUTTING, TRENCHANT, INCISIVE, CRISP. As used of things, SHARP (the common word) applies to either an edge or a point; KEEN (now somewhat rhetorical), esp. to an edge, rarely to a point; ACUTE (commonly more or less technical) applies to a point regarded as angular, but not to an edge; as, *sharp* (or *keen*) as a razor, *sharp* (not *keen*) as a needle, an *acute* leaf. As applied to that which affects the senses, SHARP is of much wider application than KEEN, which is chiefly used of cold, wind, etc.; ACUTE, in this application, is rare; as, *sharp* as vinegar, a *sharp* voice, a *sharp* flash, a *sharp* (or *keen*) wind. As applied to the senses themselves, SHARP is used esp. of sight and hearing, KEEN, of sight and smell, ACUTE, of hearing; as, *sharp*-sighted, *keen*-sighted, *sharp* ears, his hearing was still *acute,* dogs *keen* of scent. As characterizing pleasures and pains, SHARP suggests most definitely that which cuts or pierces, KEEN implies intensity, ACUTE, poignancy; as, a *sharp* pain, *keen* zest, *acute* anguish. With reference to persons or personal qualities, SHARP often implies overcleverness or trickiness, KEEN suggests shrewdness or quickness, ACUTE, penetration or nicety of discrimination; as, *sharp* practice, a *sharp* customer; a *keen* intellect, "his *keen,* worldly face" (*Dr. J. Brown*); "He is . . . rather . . . an *acute* thinker than a subtle one" (*De Quincey*); "His criticisms are always sensible, never *acute*" (*Landor*). *Sharp* comes into comparison with *cutting, trenchant, incisive,* and *crisp* with reference to language. SHARP implies esp. acrimony or sarcasm; that is CUTTING which is designed to wound the feelings; as, a *sharp* retort, a *sharp* rebuke; "Eloquence, smooth and *cutting,* is like a razor whetted with oil" (*Swift*); "[He] ridiculed [her] . . . with all the *cutting* words that his wit could find" (*Tyrrlope*). TRENCHANT implies sharp definition or forthright energy; INCISIVE, clean-cut directness; CRISP, terse or racy vigor; as, "The right word, bold and *trenchant,* is thrust into its place" (*Stevenson*); "When roused by indignation or moral enthusiasm, how *trenchant* are our reflections!" (*W. James*); *incisive* commands, an *incisive* tone; "There was about [him] . . . a something hard and crystalline, a positiveness, an *incisiveness* of view" (*M. Hewlett*); "compact in form, *crisp* and nervous in style" (*Trevelyan*); "the blithe, *crisp* sentence, decisive as a child's expression of its needs" (*W. Pater*). SHREWD implies native cleverness, or sharpness of wit or judgment, in practical affairs; SAGACIOUS, a word of more dignity, retains the implied contrast with deep wisdom or mere learning, but often suggests greater discernment or more farsighted judgment than *shrewd*; as, "[He] is . . . sensible and *shrewd*, with a considerable fund of humor" (*Smollett*); "a very *shrewd*, clever, coarse, entertaining man" (*Sydney Smith*); "the *shrewd* wisdom of an unlettered old woman" (*W. Syn. — Reserved, retiring, timid, shrinking, shamefaced, sheepish, unobtrusive, unassuming, unostentatious, demure. — SHY, BASHFUL, DIFFIDENT, MODEST, COY agree in the idea of sensitiveness to the notice or society of others. SHY implies a shrinking, whether constitutional or the result of inexperience, from familiarity or contact with others; shyness usually manifests itself in a certain reserve of manner; BASHFUL implies an instinctive or constitutional shrinking from public notice, usually expressing itself in greater or less awkwardness of demeanor, and primarily characteristic of childhood; as applied to mature persons, it connotes abnormal or excessive shyness; as, "He is a sweet lad, but as *shy* as a bird" (*Cowper*); "that *shyness* or principle of reserve which is inseparable from self-respect" (*De Quincey*); "I have a *shyness* of disposition, which looks like pride, but is not" (*Scott*); "What a curious thing *shyness* is, . . . never knowing what to say, and yet sometimes pouring out its feeling like a flood" (*Jowett*); "My sudden appearance frightened [the children] into *bashfulness*. They remained for a moment playing on their lips with their fingers, and now and then stealing a *shy* glance from under their eyebrows" (*Irving*). DIFFIDENT implies a distrust, which may or may not be warranted, of one's own ability, opinion, or powers; it gives rise to hesitation in their exercise; MODEST, without implying (like *diffident*) self-distrust, denotes an absence of all undue confidence in one's self or one's powers; as, "She was always quick and assured; Isabella slow and *diffident*" (*Jane Austen*); "Unfeigned *diffidence* of my own comparative talent" (*Coleridge*); "The *modest* men who are by *diffidence* restrained from such an enterprise" (*Cowper*); "I still shrunk from the press with the terrors of virgin *modesty*" (*Gibbon*). COY suggests assumed or affected shyness, often with the further implication of coquetry; as, "'Tis but a kiss I beg, why art thou *coy*?" (*Shak.*); "so near and yet so far — so willing and yet so *coy*" (*Frederick Harrison*); "the *coy* reticences . . . of this proposal" (*A. Dobson*). See EMBARRASS.

side chain. *Chem.* In a molecule, a branch " chain " of atoms attached to the principal chain, or to a ring.

side'-chain' the'o-ry. *Physiol. Chem.* A theory proposed by Ehrlich as a chemical explanation of immunity phenomena. In brief outline it is as follows: Animal cells and bacteria are complex aggregations of molecules, which are themselves complex. Complex molecules react with one another through certain of their side chains, but only when these side chains have a definite correspondence in structure (this accounts for the specific action of antitoxins). **A receptor** is an outlying part of the cell which is able to combine, by means of a so-called **haptophorous group**, with foreign molecules, as with a food molecule (thus helping to nourish the cell) or with a toxin molecule. Such combination stimulates the cell to produce other receptors and may at last result in overproduction, the superfluous receptors becoming detached from the cell. The so-called **immune bodies** formed in immunizing processes are detached receptors and are called also **intermediary bodies**, or **amboceptors**, because they have two haptophorous groups and act as links to bind invading cells to the **complements** (also called **addiments, alexins, cytases**) which are normally present and which when so united to the foreign cells are able to destroy them by means of a **zymotoxic group** or **toxophore group**. The amboceptor with its complement constitutes a **cytotoxin, hemolysin,** or **bacteriolysin**. Other detached receptors act as **agglutinins**, or as **precipitins**. Toxins have a **haptophorous group** (by which they combine with antitoxins) and a **toxophorous group** to which their injurious effects are due. A toxin which has lost its toxophorous group, as by heating, is called a **toxoid**. Similarly, a **complementoid** is a complement which has lost its zymotoxic group, and an **amboceptoid** is an amboceptor which has lost one of its haptophorous groups. The presence of a foreign cytotoxin leads to the production of an anticytotoxin, which may act on the amboceptor (**antiamboceptor**) or on the complement (**anticomplement**).

4. Flavorless; flat; — said of spirit, esp. rectified spirit used in the arts, in making factitious brandy, etc.

Syn. — SILENT, TACITURN, RETICENT, RESERVED. SILENT, as here compared (see NOISELESS), may imply either a transient state or a characterizing quality; TACITURN suggests habitual disinclination to speech; as, "We paused . . . and . . . hand in hand, sat *silent*" (*Tennyson*); "Genoa, where men were brave and *silent* and maidens frank like the sea" (*M. Hewlett*); "a man rather *taciturn* in speech; *silent* when there was nothing to be said; but pertinent, wise, sincere when he did speak" (*Carlyle*); "The secrets of nature have not more gift in *taciturnity*" (*Shak.*). One is RETICENT who is disposed to keep one's own counsel; RESERVED often adds to *reticent* the implication of coldness or restraint of manner; as, "He was new, and therefore immediately aroused her curiosity; he was *reticent*, and kept it awake" (*Stevenson*); "the power of holding one's tongue, which is called *reticence*" (*Jowett*); a *reserved* and distant demeanor; cf. "wrapping a cloak of *reserve* about my interest, hopes and aims" (*J. A. Symonds*); "that delicate and honorable *reserve* which, for the most part, restrains us from the public exposure of our own errors and infirmities" (*De Quincey*). See DUMB, STILL, SHY.

Myth.* One of a type of woodland deities or godlings, related to the satyrs and centaurs, and represented as part man and part horse or part goat. In the horse form they are usually more humanized than the centaurs. Like the satyrs, they are companions of Dionysus. In myth the principal *silenus* (or Silenus viewed as an individual) is sometimes described as the oldest of the Satyra, son of Hermes, or of Pan, and fosterer of the infant, and companion of the adult, Bacchus. He is represented as a short, stout, bald-headed old goat-man, or horse-man, with full beard and flat nose, and commonly tipsy. He is sometimes said to be the inventor of Pan's pipes (see PAN), and again of the double flute, being identified with Marsyas (which see). The sileni are probably of Anatolian origin. Cf. CENTAUR, 1, FAUNUS, SATYR, 1, SILVANUS, 2.

sil'i-cate (-kāt), *n.* [Cf. F. *silicate*.] *Chem.* A salt or ester of any of the silicic acids; — called specif. *monosilicate* (*orthosilicate*, *metasilicate*) or *polysilicate* (*di-*, *tri-*, *tetrasilicate*, etc.) according to the particular acid from which it is derived. In mineralogical chemistry the silicates are of great importance, forming by far the largest class of minerals. Their complexity and occurrence as isomorphous mixtures renders them difficult to classify. Dana recognizes the following divisions: (1) **disilicates**, derived from $H_2Si_2O_5$, oxygen ratio 4:1; and **polysilicates**, from H_4SiO_4, oxygen ratio 4 : 1; (2) **metasilicates**, or **bisilicates**, from H_2SiO_3, oxygen ratio 2 : 1; (3) **orthosilicates**, or **unisilicates**, from H_4SiO_4, oxygen ratio 1 : 1; (4) **subsilicates**, having an oxygen ratio of less than 1 : 1 and regarded in most cases as basic salts of acids mentioned above. There are also many **hydrous silicates**, as zeolites and hydrated decomposition products.

F. *silicique*.] *Chem.* Pert. to, derived from, or resembling, silica; specif., designating compounds of silicon; as, *silicic* acid.— **silicic acid**, any of various acids, all of which may be regarded as hydrated forms of silica, SiO_2. The normal acid, $Si(OH)_4$, usually called *orthosilicic acid*, can be obtained in solution by treating a solution of potassium or sodium silicate (water glass) with hydrochloric acid. It readily assumes a gelatinous form, but on drying loses water, yielding *metasilicic acid*, H_2SiO_3, which is prepared in glassy form by drying over sulphuric acid. From the above *monosilicic acids* are derived many *polysilicic acids*, by loss of water from two or more molecules. They are called *di-*, *tri-*, *tetrasilicic acids*, etc., according to the number of silicon atoms in the molecular formula. Thus, $H_2Si_2O_5$ is derived from the meta acid. All silicic acids yield silica on heating. See SILICATE. — **s. oxide**, silica.

1. The fine, strong, lustrous fiber produced by various insect larvæ, generally to form their nest or cocoon; esp., that produced by certain caterpillars (the silkworms) and used for weaving into fabrics. The caterpillars secrete the silk as a viscous fluid in two large glands in the lateral parts of the body. These communicate by ducts with the spinneret on the labium (under lip). The silk from the two glands is united in a single thread, which quickly hardens. The caterpillar spins or produces this thread and winds it about itself so as to form a covering or cocoon in which it passes the pupa stage. In the case of the domesticated silkworm much of the thread may often (after softening and loosening the cocoon by immersion in warm water) be reeled off in a single piece (see also RAW SILK, 1). Raw silk contains 20–30 per cent of sericin, or silk glue, and is harsh and stiff. Boiled, or boiled-off, silk, is fine, soft, and white, with all glue removed by steeping and boiling in soap baths; écru silk is harsher, and has not over 5 per cent of its original weight removed. See also SOUPLE SILK, etc.

2. Thread or cloth made of the above material.

3. A thread or filament resembling silk, produced by some other animal. The threads of some spiders' webs are almost as strong as those produced by the silkworms and have been similarly used, though such use has not been made commercially successful. The byssal threads of a mollusk (the pinna) have also been woven into cloth.

silk'worm' (sĭlk'wûrm'), *n.* [AS. *seolcwyrm.*] The larva of any of certain moths, which spins a large amount of strong silk in constructing its cocoon before changing to a pupa. The common domesticated silkworm is the larva of a bombycid moth (*Bombyx mori*) which is yellow and measures about an inch and a half across the extended wings. It is supposed to be a native of China, but has been domesticated for many centuries, and is no longer known in the wild state. Its cultivation was introduced into western Asia and Europe early in the Christian Era, and into America during the colonial period. It feeds on the leaves of the white and certain other species of mulberry and of the Osage orange. Many varieties or races of the worm have been developed by Asiatic and European breeders, which may differ in the number of annual generations (cf. BIVOLTINE, TRIVOLTINE). A comparatively small amount of silk is furnished by the larvæ of various moths of the family Saturniidæ, as the tussah silkworm (*Antheræa mylitta*) of India, the yamamai silkworm (*A. yamamai*) of Japan, and the pernyi silkworm (*A. pernyi*) and the ailanthus silkworm (*Philosamia cynthia*) of China. The last named has been introduced into Europe and North America. In America unsuccessful efforts have been made to use commercially the silk of various native species.

Si·lu′ri·an (sĭ-lū′rĭ-ăn; sī-), *a.* **1.** Of or pert. to the Silures. **2.** *Geol.* Designating, or pert. to, the Paleozoic period between the Ordovician and Devonian. The known Silurian formations are chiefly of shallow-water origin, as the salt beds of New York and Ohio. Most types of invertebrate marine life flourished. Coral-reef building began. In the latter part some great crustaceans appeared. The Silurian system, as named by Murchison, included all Paleozoic beds earlier than the Devonian, and was divided into the **Upper Silurian** and **Lower Silurian**. The lower part of the Lower Silurian, with some underlying beds, was later separated as the *Cambrian*. The term *Ordovician* has now largely replaced *Lower Silurian*, leaving *Silurian* to apply only to the former Upper Silurian. The members are mostly voracious freshwater carnivores generally lurking on or near the bottom. See CATFISH, BULLHEAD, 1 a, SHEATFISH. — **si·lu′rid** (sĭ-rĭd), *a. & n.*

The Hindus introduced the improvement of considering the half chord of the arc. *Munk.*] **1.** *Math.* **a** Formerly, the perpendicular drawn from one extremity of an arc of a circle to the diameter drawn through the other extremity. **b** Now, the ratio of the length of this perpendicular (reckoned from the diameter to the circle) to that of the radius of the circle, taken + or — according as the perpendicular is drawn upward or downward from the diameter (in positive or in negative sense). The sine of a plane angle is the sine of the arc subtending that angle at the center of a circle of unit radius; or it is the ratio of the side opposite the angle, in a right-angled triangle, to the hypotenuse, or of the area of a parallelogram having such angle to that of a rectangle having adjacent sides equal to the sides bounding the angle. Hence, the sine of a solid angle is taken as the ratio of the volume of a parallelepiped having such an angle to that of a cuboid with three concurrent edges equal to the edges bounding the angle; and so on for higher spaces and angles. Algebraically, the sine is defined by the infinite series $\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \ldots$. See TRIGONOMETRICAL FUNCTION.

skep'ti-cism, scep'ti-cism (-tĭ-sĭz'm), *n.* [Cf. F. *scepticisme.*] **1.** An incredulous or doubting state of mind; the mental attitude of the skeptic. **2.** *Philos.* The doctrine that no fact or principle can be certainly known, or that all knowledge is uncertain; the position that no fact or truth can be established on philosophical grounds; also, the method of suspended judgment, destructive criticism, or systematic doubt characteristic of skeptics. *Skepticism* as a point of view is opposed to *dogmatism*, and appears as a reaction from it. The earliest skeptics were the Greek Sophists, who made "the worse appear the better reason," and the Pyrrhonists, who formed the first systematic school of Skepticism (see PYRRHONISM, SOPHIST). The Middle Academy (see ACADEMY, 1), and later writers of antiquity, esp. Sextus Empiricus (2d century A. D.), also represented skeptical thought. In the main, ancient skepticism was based upon the doctrines of the relativity of sense, knowledge, and human belief (cf. RELATIVITY OF KNOWLEDGE). The skeptical arguments were made use of by many Christian writers to prove the unreliability of human reason and the necessity for an authority for any valid knowledge. Skepticism as an element or stage in philosophic method was used both by St. Augustine and Descartes, who derived the necessity of individual existence from the mere attempt to doubt it (cf. COGITO ERGO SUM), while Hegel maintained that the skeptical is a necessary stage of every philosophic evolution. Modern skepticism, other than religious, finds its chief exponents in David Hume (see HUMISM) and Montaigne; but the skeptical attitude enters largely into all scientific method. Cf. ECLECTICISM

The outer, the *epidermis* (which see), or *cuticle*, is composed of stratified ectodermal epithelium, and is without nerves or blood vessels. Only the deeper layers of cells of the epidermis are capable of growth. The more superficial layers usually change into horny material and wear away, or are cast off little by little, as in man, or they may be shed as a coherent membrane at longer intervals, as in snakes.

Glands (in man the sebaceous glands and sweat glands, the orifices of the latter being called *pores*) open on the skin in most vertebrates, but are almost wanting in reptiles. The inner layer of the skin, the *derma, dermis*, or *corium*, is mesoblastic in origin and composed mainly of connective tissue. It contains abundant blood vessels and nerves. In many animals (armadillos, many reptiles, most fishes) bony plates or calcified scales develop in the dermis. In invertebrates the commonest type of skin consists of a single layer (the *hypodermis*) of columnar ectodermal cells, which rest on an underlying basement membrane, and secrete an external noncellular cuticle.

It is cartilaginous in primitive forms (cyclostomes and elasmobranchs) and in the embryos of all, but in most vertebrates the cartilage is mostly replaced by bones and the structure made more complete by the union with it of other bones developed in membrane. Some of the bones always become firmly sutured or ankylosed together to form a case (the *cranium*) for the brain. The ossification of the cartilaginous cranium of the embryo forms the elements of the sides, base, and rear of the bony cranium, but its roof is formed chiefly of membrane bones (the *frontal* and *parietal* bones). The bony elements forming the capsules of the nose and ear are united with the cranium, but the capsule of the eye (the *sclerotic*) remains movable and usually entirely unossified, although the adjacent bones of the skull form a socket (the orbit) to contain it. The jawbones are derived from the first visceral arch (see VISCERAL ARCHES) of the embryo, usually supplemented by membrane bones. The upper jaw may be firmly (as in mammals) or movably (as in most fishes) connected with the cranium; the lower jaw is always movable. *Skull* often denotes only those parts immovably united with the cranium. Syn. — SMELL, ODOR, SCENT, FRAGRANCE, PERFUME, AROMA. PERFUME belongs either to natural or prepared objects, and may be either light or heavy; as, "filling the chilly room with *perfume* light" (*Keats*); "A soft and solemn-breathing sound rose like a steam of rich distilled *perfumes*" (*Milton*). AROMA suggests a distinctive, often delicately spicy, odor; it is frequently used in a fig. sense; as, the *aroma* of coffee; "to enrich the air as with some choice *aroma*" (*W. snake (snāk), *n.* [AS. *snaca*; akin to LG. *snake*, *schnake*, Icel. *snākr*, *snōkr*, Dan. *snog*, Sw. *snok*; of uncert. origin.]
1. Any of numerous limbless reptiles having a very elongate body, that constitute the group Ophidia, ranking as an order, or as a suborder of the Squamata. Geologically, the snakes are of rather recent origin. They are distinguished by the complete absence of the limbs and their supporting arches, except for traces of the hind limbs or pelvic girdle in a few forms; by certain peculiarities of the cranial bones; and especially by the structure of the jaws, the branches of the mandible being generally connected in front by an elastic ligament, and the upper jawbones so connected that the mouth is usually very distensible. Snakes have the tympanum of the ear wanting and the eye permanently covered with a transparent membrane representing the nictitating membrane, but no movable eyelids. One of the lungs is usually reduced or wanting. Reproduction is ovoviviparous or oviparous. The bite of most snakes is not poisonous, but some have certain of the salivary glands modified into poison glands and some of the upper teeth developed into grooved or even tubular fangs, and are among the most dangerous of animals. Snakes are almost exclusively predaceous, generally refusing all but living prey, which consists of large insects, small mammals, birds, and lizards, etc. These they swallow whole, in some cases alive, in others after poisoning them, or strangling them in coils of the body. Though most snakes live on the ground, or in holes or crevices, some are burrowers, some arboreal, and others aquatic or even truly marine in habits. Most of them have the belly covered with broad transverse plates to each of which the ends of a pair of ribs are attached, and movements of the ribs and plates help in locomotion, which is, however, performed chiefly by lateral undulations of the body (pressing against inequalities on the surface, stems of plants, etc.). Most snakes are not only harmless to man, but often useful. None of them can sting with the tail or with the tongue. The name is popularly extended to snakelike limbless lizards, as the *glass snake*. See also CONGO SNAKE, SERPENT, 1.

so'cial-ism (-ĭz'm), *n.* [Cf. F. *socialisme.*] **1.** A political and economic theory of social reorganization, the essential feature of which is governmental control of economic activities, to the end that competition shall give way to coöperation and that the opportunities of life and the rewards of labor shall be equitably apportioned. Its various theories and various programs have received many distinctive names. Such are *Christian socialism*, promulgated in England by Thomas Hughes, Charles Kingsley, F. D. Maurice, and others; *Owenism* and *Fabianism* in the same country; *collectivism*, *Saint-Simonianism*, and *Fourierism* in France; the *communism* of the Brook Farm and the *nationalism* of the followers of Edward Bellamy in America; the *socialism of the chair*, *state socialism*, and the *social democracy* of Germany. Often, however, *socialism* is used to denote specifically the economic theories developed especially by Ferdinand Lassalle and Karl Marx, advocating the annulment of private ownership of capital and land, and maintaining that all values are the creation and just due of labor. *Socialism* of a more idealistic sort appears in the antiutilitarian and æsthetic theories of production of Ruskin and William Morris, which have also found some following in America. In questions of policy, opportunist or conservative socialists are distinguished from revolutionists or radicals. The latter have been more or less associated with anarchists, and *socialism* is often confounded with *anarchism* (which see). *Socialism*, however, advocates a powerful central government, *anarchism* opposes all government as evil; both, however, are forms of *communism*, sharing the ideal of a coöperative society.

The word *socialism* dates from about 1835, and seems to have originated in several quarters simultaneously. Leroux claims to have invented it as an antithesis to individualism.
A. T. Hadley (*Dict. of Philos.*).

For the purposes of modern discussion, *socialism* may be described as that policy which aims at a more equal distribution and, in subordination thereto, a better production of wealth by means of the direct action of the central authority.
James Bonar (*Encyc. Brit.*).

His tenets were that Christ was a man miraculously conceived by the Virgin Mary; that the Holy Spirit is a power or influence exerted by God; that human sin was the imitation of Adam's sin, and salvation the imitation and adoption of Christ's virtue; that the Bible is to be interpreted by human reason.

sol'mi-za'tion (sŏl'mĭ-zā'shŭn), *n.* [F. *solmisation*, fr. *solmiser* to sol-fa; — so called from the musical notes *sol, mi.* See SOL-FA.] *Music.* Act, practice, or system of using a set of syllables to denote the tones of a scale; sol-fa notation; solfeggio. A system of solmization, based on the syllables τω, τα, τη, τε, for the four notes of the tetrachord, was used by the Greeks of the Roman Empire and perhaps earlier. The most important system is that ascribed to Guido d'Arezzo, an 11th-century monk. The following first phrases of an ancient hymn to St. John the Baptist began on the ascending tones of the major scale:

Ut queant laxis *Resonare* fibris,
Mira gestorum *Famuli* tuorum,
Solve polluti *Labii* reatum,
Sancte Joannes

The six initial syllables, accordingly, were applied to the tones of the hexachord. When a melody exceeded the compass of one hexachord, the syllables were changed for the new hexachord by "mutation." See GAMUT, *Illust.* When the medieval hexachord was supplanted by the octave, the syllable *si* (perhaps from the initial letters of the last line) was added for the seventh tone. Except in France, *do* has supplanted *ut* as more sonorous. In France and Italy the syllables *ut* (or *do*), *re*, etc., have become identified with the notes C, D, etc., by what is called the *fixed do* system. In England and America they are used as a transposable scale pattern by the *movable do* system, *do* being used for any tone taken as a keynote. Sharps and flats have been given names, in this system, made by adding *i* and *e* to the initial consonants of these syllables; thus, *di* for *do*♯, *me* for *mi*♭. The minor scale is solmizated either as in the major scale but beginning with *la*, or beginning with *do* and using the modified syllables; thus, *do, re, me*, etc. A modern extension of solmization is the *tonic sol-fa.*

See SOUND a noise.] *Music.* An instrumental composition, usually in more than one movement ; — used in the 17th and 18th centuries in distinction from *cantata.* Two types of sonata were recognized : the *sonata da chiesa,* or church sonata, inclining to grave airs contrapuntally treated ; and the *sonata da camera,* or chamber sonata, resembling the suite. **b** An extended composition in cyclic form, for one or two instruments, and in three or four movements which are contrasted in rhythm but related in tonality and properly have an organic unity of sentiment and style. The movements are typically as follows: (1) an allegro, or quick movement in the distinctive sonata form (see def. **a** below), which may have a short slow introduction ; (2) an adagio, largo, andante, or other slow movement, either in the song or variation form ; (3) the lighter minuet or (the more modern) scherzo, sometimes with appended trio ; (4) the quick finale, often in rondo form.

sonata form. *Music.* **a** A type of musical structure distinctive of the sonata. It is based upon two themes or subjects, presented in different keys, often with transitional episodes, and conforming substantially to the following plan : (1) the **exposition,** giving out the principal subject in the tonic key, and the secondary subject usually in the dominant key if the tonic key is major, otherwise in the relative major ; (2) the **development,** giving a full thematic working out of one or both subjects ; (3) the **recapitulation,** repeating both subjects in the original key, and ending with a coda. **Sonata formula** has been suggested for this sense to distinguish it from the next. **b** An extended form in several movements, typically as described under SONATA **b**, of which sonata form is used not only in the sonata proper, as for piano, organ, violin, etc., but in the concerto, string quartet, and other chamber music for more than one or two instruments, and in the symphony.

The sonnet is thought to be suited for the concise treatment of an isolated sentiment or reflection, of which the exposition often flows to a climax in the octave, and the conclusion follows with an answering ebb in the sestet.

The use of such terms as "breath" (Heb. *nephesh*, Gr. πνεῦμα, Lat. *anima*, *spiritus*) and "shadow," or "shade" (Egypt. *ba*, Gr. σκιά, Lat. *umbra*), shows the nature of the earliest conceptions of the soul. The Egyptian distinction of *ba* and *chu* (see BA), *soul* and *spirit* (Gr. and Biblical ψυχή and πνεῦμα) dates from the earliest times, and the characteristic Egyptian conception of the divine origin of the soul, of its earthly life as a warfare between good and evil, and of its future state as determined by a divine judgment, outlines also the main belief of all Western peoples. The Christian conception of the soul derives from the Greek as well as from the Bible. "Soul is throughout a great part of the Bible simply the equivalent of 'life' embodied in living creatures. In the earlier usage of the Old Testament it has no reference to the later philosophical meaning — the animating principle, still less to the idea of an 'immaterial nature' which will survive the body." — *Dict. of the Bible (Hastings).* The more exact determination of the Christian conception was reserved for the Church Fathers, especially St. Augustine, who taught that it is simple, immaterial, and spiritual, devoid of quantity and spatial extension. He argued its immortality from the fact that it is the repository of imperishable truth; and he distinguished its lower, appetitive and sensuous, from its higher, or spiritual, volitional, and cognitive, nature. Descartes, with his theory of bodily automatism and his doctrine that the essential nature of the soul is rational thinking, which the brutes cannot share, gave a new form to the problem of the soul's nature. Three types of conception have been formulated in answer. First, the soul has been treated as an entity or subject manifested especially in man's volitional and thinking activities; it is the subject of the experience mediated by the body; it is not the mind, but that which thinks and wills. Second, the soul is identified with the mind or with conscious experience; this is the usual sense of the word in psychology and is the general conception of idealists. Third, the soul is treated as a function, or the sum of the functions of the brain: thus Pierre J. G. Cabanis (1757-1808) taught that the brain secretes thought as the stomach digests food. Some conceptions, such as that of Fechner that the soul is the whole unitary spiritual process in conjunction with the whole unitary bodily process, appear to stand midway between the idealistic and materialistic views. Cf. ANIMISM, TRANSMIGRATION. See GHOST, *n.*, 1, SPIRIT.
2. Hence, the psychical or spiritual nature of the universe conceived as related to the physical world as the human soul to the human body; the world soul.
3. Man's moral and emotional nature as distinguished from his intellect; hence, expression which effectively presents or arouses emotion and sentiment.
4. The seat of real life, vitality, or action; the animating or essential part. "The hidden *soul* of harmony." *Milton.*
5. The leader; inspirer; moving spirit; the heart; as, the *soul* of an enterprise; the *soul* of kindness.
6. Courage; spirit; fervor; affection, or any other noble manifestation of the heart or moral nature.
7. A human being; a person; — a familiar appellation, usually with a qualifying epithet; as, poor *soul*.
8. A disembodied spirit, or a spiritual being,
That to his only Son . . . every *soul* in heaven
Shall bend the knee. *Milton.*
Syn. — SOUL, SPIRIT are often convertible terms, esp. in their denotation. But in ordinary usage (for technical distinctions see defs.) SOUL is apt to connote greater depth of feeling or sentiment than SPIRIT, which suggests more strongly vital energy or (often) independence of bodily form; as, "God is *soul*, *souls* I and thou; with *souls* should *souls* have place" (*R. Browning*); "Speak to Him, thou, for He hears, and *spirit* with *spirit* can meet" (*Tennyson*); "Call the world, if you please, 'The vale of *Soul* making' . . . I say 'Soul making' — *Soul* as distinguished from Intelligence" (*Keats*); "Difficulties nerve the *spirit* of a man" (*id.*); "When my lips just touched your cheek — touch which let my *soul* come through" (*R. Browning*); "And our *spirits* rushed together at the touching of the lips" (*Tennyson*);

The question whether *space* is real apart from space-filling objects, that is, whether it is a receptacle for things or an attribute of them, dates from early times. The antithesis of these two views is complicated in modern discussions by the question of the subjective (ideal) or objective (noumenal) reality of space. Many theories have been advanced. First, according to common thought, space is a real (noumenal) receptacle, intrinsically void; this was Newton's view. Second, space is the essence of bodily substance (Descartes's conception) or an attribute of substance (Spinoza). Third, space is a mental construction due to the gradual coördination of sensations, especially of sight and motion; this is Berkeley's view and the usual conception of recent psychologists. It is held in two forms, some authorities maintaining that space is merely a product of the coördination of sense experience, others that it is a quality of sensations themselves. Fourth, space is an a priori form into which sensuous experience necessarily falls; this is the Kantian view. A fifth view maintains the existence of two kinds, distinguishing *ideal* or a priori form from *real* or physical space and admitting both. *Mathematical* spacing is to be distinguished. The reasoning Aristotle ("Physics," Book IV.) held the view commonly accepted in modern times of space as the logical condition of the existence of bodies; space being "that without which bodies could not exist, but itself (space) continuing to exist when bodies cease to exist;" space possesses magnitude or extension, though itself is not a body — "for in case it were a body then two bodies would exist in the same place." He urged that inclosed places may be contained and moved in larger including places — a ball in a box, the box in a house, the house in a town, the town on the earth, etc; but all places are in one continuous space, an ultimate environment, πέρας, which contains all movable things and is not movable itself. *W. T. Harris.*

2. *Math.* Continuous extension in which objects may exist and change their position. In Euclidean geometry we infer from our restricted experience that space has three dimensions, is unlimited in extent in these dimensions, and has the same properties in all its parts. Its properties are further defined by certain axioms or postulates formulated by Euclid. The non-Euclidean geometer, by postulates different from those of Euclid, yet not contradicted by our limited experience, develop a self-consistent explanation of the phenomena of space; or he may assume hypotheses which apparently do not agree with our experience and from these build up an equally self-consistent system of geometrical propositions, true for his imagined space. An **n space, extent,** or **manifold** is one of **n** dimensions

An **expanding space** is one automatically cast on the monotype machine, of such width that, with other similar spaces, it will justify the line of type in which it occurs; — opposed to *fixed space*, a space of a particular fixed width.

spe'cies (spē'shēz; -shĭ-ēz; 277), *n. sing. & pl.* [L., a sight, outward appearance, shape, form, a particular sort, kind, or quality, a species. See SPICE, *n.;* cf. SPECIE, SPECIAL.] **1.** A mental image, phantasm, or sensuous presentation; an idea or object of thought considered as the similitude of an object in nature, whether in the guise of a modification of sense or of a purely intellectual correlative of the natural object; in loose usage, form; aspect; appearance. Scholastic epistemology, as developed by Thomas Aquinas, is a doctrine of intentional species. According to this view, the *species* is first the ‖ **spe'ci-es sen-si'bi-lis** [spē'shĭ-ēz sĕn-sĭb'ĭ-lĭs] (*sensible species*) operating in sense knowledge. It originates as sense action (conceived as physical motion and psychical affection), in which form it is called the ‖ **spe'ci-es impres'sa** [ĭm-prĕs'ä] (*impressed species*), while the translation of this activity or affection by the mind, that is the sensuous construction or representation, is termed the ‖ **spe'ci-es ex-pres'sa** (*expressed species*). But the sensible species ends in sense knowledge; intellectual cognition is obtained only through the ‖ **spe'ci-es in-tel'ĭ-gi'bi-lis** [ĭn-tĕl'ĭ-jĭb'ĭ-lĭs] (*intelligible species*). In so far as this is conceived as an affection of the active intellect

abstracting the intelligible element of the sensible species, it is termed the ‖ spe'ci-es in-tel'li-gi'bi-lis im-pres'sa, while the product or mental translation of the process is the true image or conception of the original object, and is termed the ‖ spe'ci-es intel'li-gi'bi-lis ex-pres'sa. Thus the processes leading to sense knowledge and to intellectual knowledge precisely correspond. Many writers, however, have used *species* as equivalent to effluvium or to phantasm.

4. *Logic.* A group of individuals having common attributes, and designated by a common name; a conception subordinated to another conception, called a genus, or generic conception, from which it differs in having or comprehending more attributes, and extending to fewer individuals.

Every class which is a real kind, that is, which is distinguished from all other classes by an indeterminate multitude of properties not derivable from one another, is either a genus or a *species*. *J. S. Mill.*

5. *Biol.* A category of classification lower than a genus or subgenus and above a subspecies or variety; a group of animals or plants which possess in common one or more characters distinguishing them from other similar groups, and do or may interbreed and reproduce their characters in their offspring, exhibiting between each other only minor differences bridged over by intermediate forms (see SUBSPECIES) and differences ascribable to age, sex, polymorphism, individual peculiarity or accident, or to selective breeding by man; a distinct kind or sort of animal or plant. Until the acceptance of the theory of evolution a species was regarded as being the offspring of a single specially created ancestor or pair; hence, each species was considered definitely separated from other species, and usually as unchanging from one generation to another. Individuals intergrading between two supposedly distinct species were commonly considered as hybrids or as abnormal individuals whose peculiarities approached the normal characters of the other species. The theory of evolution, however, involves the conception that species are not unchanging, but that they have developed and are developing from preëxisting and different species, also that this process is in many cases still going on. With the abandonment of the doctrine of separate creation of species, the term *species* loses much of its theoretical importance. In the case of closely allied groups, the prevailing practice is to recognize those as distinct species whose members are not known to, or are assumed not to, intergrade with some other species, even if the characters distinguishing them be very slight, while those which intergrade are regarded as only subspecies. Cf. EVOLUTION, 7 **b**, MUTATION, 6, SUBSPECIES, NOMENCLATURE, 3.

The *species* is the union of individuals descending one from the other or from common parents, and of those who resemble them as much as they resemble each other. *Cuvier.*

A *species* is the smallest group to which distinctive and invariable characters can be assigned. *Huxley.*

A *species* is the abstract central point around which a group of variations oscillate. *Encyc. Brit.*

Since the thermal capacity of water is not the same at all temperatures, the latter of these two definitions is to be preferred, because it expresses the thermal capacity of the substance per unit mass in terms definitely related to units of energy. Specific heat of a gas at constant pressure is equal to the specific heat at constant volume plus the work done in the former case by the expanding gas. — **s. inductive capacity**, *Elec.*, the ratio of the electric strain to the electric stress in a dielectric acted on by a uniform electric force which produces uniform electric strain or displacement. — **s. legacy**, *Law*, a bequest of a particular thing or part out of the testator's estate, as of a specified animal or piece of furniture. — **s. lien.** See LIEN. — **s. magnetic rotation.** See MAGNETIC ROTATION. — **s. name.** See NOMENCLATURE, 3. — **s. performance**, *Law*, the performance of a contract according to its terms, or substantially so; — used chiefly with reference to such performance as decreed by a court of equity, where the common-law remedy of damages would be totally inadequate and the specific performance not unjust to the defendant. Also, a decree ordering specific performance. — **s. refractive power**, a value which takes into account the relation between the refractive index (n) of a substance and its density (d), as expressed either by the empirical formula $\frac{n-1}{d}$ or by the theoretically derived formula $\frac{n^2-1}{(n^2+2)d}$ — called also *constant of refraction*. — **s. reluctance**, *Elec.*, the reluctance of a centimeter cube of a substance; reluctivity. — **s. resistance**, *Elec.*, resistance across opposite faces of a centimeter cube of a substance; resistivity. — **s. rotation** *or* **rotatory power**, the optical rotation or power to turn the plane of polarization of light exhibited by a substance, as expressed by the formula $\frac{100a}{lpd}$, where a is the observed angle of rotation, l the length through which the light passes, p the per cent by weight of the substance present, and d the density of the substance or solution. — **s. security.** See SECURITY, 3. — **s. stain**, *Microscopy*, a pigment, used in histology and microchemistry, having a peculiar affinity for certain structural elements or chemical compounds. — **s. volume**, *Physics & Chem.*, the quotient got by dividing unity by the specific gravity; the reciprocal of the specific gravity. 2. *Physics.* An image formed when a beam of light, or, in general, of radiant energy, is subjected to dispersion so that its rays are arranged in a series in the order of their wave lengths. Thus, by causing white light to pass through a prism, a *spectrum* is obtained in which several colors form a series, from deepest red (about 770 $\mu\mu$, i. e. millimicrons, wave length) through orange, yellow, green, and blue to deepest violet (about 390 $\mu\mu$). The **visible, ocular,** or **chromatic, spectrum** consists of all rays which affect the eye; they lie between the limits just given. The **actinic,** or **chemical, spectrum** comprises those rays (lying chiefly in the violet and ultraviolet regions) which are capable of chemical action, as in photography; the **thermal spectrum,** or **heat spectrum,** is principally composed of dark, infra-red rays. Incandescent solids and liquids, and gases under high pressure, give a **continuous spectrum,** or one having no gaps. A **band spectrum** or **line spectrum** (one characterized by bands or lines) is produced either by an incandescent gas under low or ordinary pressure, in which case the lines or bands are *bright* with dark spaces between, or by light which has suffered selective absorption by passage through a layer of gas, liquid, or solid, the places of the absorbed rays being marked by *dark* lines or bands. The latter kind is called the **absorption spectrum** of the medium as distinguished from its **emission spectrum** (one produced by it as the source). The bright lines in the emission spectrum of a gas occupy the same position as the dark lines in its absorption spectrum. A **pure spectrum** is one the color tones of which are not appreciably mixed by the overlapping of the successive monochromatic images of the spectroscopic slit. The purity of the spectrum increases as the width of the slit is diminished. A **fluted spectrum** is one characterized by periodically recurring groups of lines or narrow bands, which give it a fluted appearance, as in the spectra of some stars. Spectra are known, according to the means used to produce dispersion, as **prismatic** (with a prism or train of prisms) or **diffraction** (as with a grating); and according to the source of the light as solar, stellar, flame, gaseous, etc. A **spark spectrum,** produced by the electric spark discharge, shows lines due to the volatilization of the materials of which the terminals are composed. A **normal spectrum** is one in which the different colors or parts are spaced proportionally to their wave lengths, as when formed by a diffraction grating (in prismatic spectra the violet has relatively more space than the red). A **comparison spectrum** is one formed contiguous to the spectrum under observation, and corresponding to it in wave length for wave length. See SPECTROSCOPE, LIGHT, *n.*, 1, FRAUNHOFER LINES.

Sper'ma-toph'y-ta (-tŏf'ĭ-tȧ), *n. pl.* [NL.; *spermato-* + Gr. *φυτόν* plant.] *Bot.* A phylum embracing the highest plants, or those that produce seeds; the seed plants, or flowering plants. They form the most numerous group, including over 120,000 species. In general, the group is characterized by the marked development of the sporophyte, with great differentiation of its parts (root, stem, leaves, flowers, etc.); by the extreme reduction of the gametophyte; and by the development of seeds. All the Spermatophyta are heterosporous; fertilization of the egg cell is either through a **pollen tube** emitted by the microspore or (in a few gymnosperms) by spermatozoids. The phrase "flowering plants" is less distinctive than "seed plants," since the conifers, grasses, sedges, oaks, etc., do not produce flowers in the popular sense. For this reason the terms *Anthophyta*, *Phænogamia*, and *Phanerogamia* have been superseded as names of the phylum by *Spermatophyta*.

sper'ma-to-zo'id (-tō-zō'ĭd), *n.* [*spermatozoön* + Gr. *εἶδος* form.] **1.** *Bot.* A motile male gamete or male sexual cell, usually developed within an antheridium, and liberated in the presence of water, in which it swims freely by means of cilia, being conducted or attracted by various devices to the egg, or oösphere, with which it ultimately fuses. This type of gamete occurs among oögamous algæ, throughout the mosses, hepatics, and ferns, and in certain gymnosperms. It is rounded in the lower plants, club-shaped or filamentous in the higher, and bears two or more cilia at the anterior end, thus differing from the functionally similar spermatozoön of animals. See GAMETE. **2.** *Zoöl.* A spermatozoön. *Obs. or R.*

sper'ma-to-zo'ön (-ŏn), *n.*; *pl.* -ZOA (-ȧ). [NL.; *spermato-* + Gr. *ζῷον* an animal.] *Zoöl.* A male sexual cell or sperm cell of an animal, whose function is the fertilization of the egg. See FERTILIZATION, 2. The spermatozoa of different animals vary much in form, but are commonly very minute relatively to the eggs, and capable of more or less active spontaneous movement by which they approach and enter, or fuse with, the egg. They are discharged in a fluid (semen) or in gelatinous masses or capsules (spermatophores). Most frequently they have an oval or elongated head consisting of a nucleus with but little cytoplasm, and a long tail, or flagellum, with which they swim, which is connected to the head by a structure called the middle piece. They are produced in the male reproductive gland (testis or spermary), usually in enormous numbers. See SPERMATOGENESIS, SPERMATID.

They are related to the marmots and the true squirrels, but are much smaller than the marmots and mostly have shorter, coarser fur than the squirrels. They inhabit open prairies, arid regions, and mountains, living in colonies and doing great damage to crops. Most of them hibernate, and all have internal cheek pouches for carrying food. The best-known Old World species is the *suslik*. A common species of the Great Plains of the United States is the striped spermophile (*C. tridecemlineatus*), striped with reddish brown and buff. A species (*C. franklini*) of the Mississippi Valley and another (*C. beecheyi*) of California are larger and grayish.

The most famous Greek sphinx was that of Thebes, whose habit was to propose a riddle to all passers and upon their failure to guess it to destroy them. The Thebans offered the hand of Jocasta and the throne of Thebes to the man who would rid them of the monster; Œdipus (which see) guessed the riddle, the Sphinx slew herself, and he thus became king. The riddle is said to have been: What creature walks in the morning upon four feet, at noon upon two, at evening upon three? The answer is: Man, as a baby on hands and knees, later on his feet, and in old age with a staff.

The Sphinx was mainly a local Theban bogy, but she became the symbol of ocular divinity. *J. E. Harrison.*

The huge sphinx (often "the Sphinx") near the pyramids of Gizeh has a man's head and the recumbent body of a lion. It is 172 ft. long and 66 ft. high; is partly hewn from the solid granite, and partly built up; and had a small temple built against the breast between the fore paws. spinal accessory nerves, the eleventh pair of cranial nerves in the higher vertebrates. They originate chiefly from the spinal cord in the cervical region and pass forward into the skull, from which they emerge in company with the pneumogastric nerves and supply certain muscles of the shoulder, but comprise also filaments arising from the medulla which join the pneumogastric nerves. — **s. arteries**, *Anat.*, branches of the vertebral artery which supply the spinal cord and its membranes and adjacent structures. They arise as branches of the vertebral artery, but anastomose and are reënforced or continued by branches of other arteries which enter the intervertebral foramina. — **s. canal**, the canal (covering the spinal cord) formed by the series of neural arches of the vertebræ. — **s. column**, *Anat. & Zoöl.*, the articulated series of small bones or vertebræ (connected by ligaments and separated by more or less elastic intervertebral tissue) which in nearly all vertebrates forms the supporting axis of the body and a protection for the spinal cord, extending from the hind end of the skull through the median dorsal part of the body, and to the end of the tail; the backbone or spine; in a broad sense, the axial skeleton of the trunk and tail of a vertebrate. In the lowest vertebrates and in the embryos of all higher forms the spinal column is represented by an elastic rod of cellular tissue (the *notochord*) (which see). This is inclosed in a fibrous sheath which also extends up and forms a sheath for the spinal cord. In this sheath cartilaginous or bony pieces develop, and commonly unite (in various ways in the different groups) to form a longitudinal series of bones, the vertebræ (cf. ARCUALIA). The notochord may persist throughout life, running through the middle of the bodies of the vertebræ, but in the higher vertebrates it becomes almost completely obliterated in the adult. In the higher vertebrates five regions (differing in the character of their vertebræ) are usually recognizable in the spinal column. These (with the number of vertebræ normally present in each in man) are as follows: cervical (7); dorsal (12); lumbar (5); sacral (5 fused together); coccygeal, or caudal (4 fused together). — **s. cord**, in vertebrates, the thick longitudinal cord of nervous tissue which extends along the back, dorsal to the bodies of the vertebræ and inclosed in a canal (the **spinal canal**) formed by their neural arches. In front it is continuous with the medulla oblongata of the brain, and it gives off at intervals pairs of nerves, the **spinal nerves** (which see), to the various parts of the trunk and limbs. It serves not only as a pathway for nervous impulses to and from the brain, but as a center for carrying out and coördinating many reflex actions independently of the brain, the importance of the brain relatively to the spinal cord being less in the lower than in the higher vertebrates. In cross section the spinal cord is more or less elliptical, with a deep median fissure on the ventral side. It is composed largely of white matter, consisting of more or less distinct groups (**columns and tracts**) of longitudinal fibers; but there is a large central core of gray matter (containing nerve cells), somewhat **H**-shaped in cross section, the branches of the lateral masses of gray matter being called the **horns**, or **cornua**. The center of the gray matter is pierced by a small longitudinal canal originally continuous with the ventricles of the brain and running the whole length of the cord, but often nearly obliterated in adult man. For the origin of the spinal cord, see NERVOUS SYSTEM. — **s. foramen**, the opening (forming a part of the spinal canal when the vertebræ are articulated) under the neural arch of a vertebra. — **s. ganglion**, *Anat. & Zoöl.*, the ganglion on the dorsal root of a spinal nerve. — **s. marrow**, *Anat.*, the spinal cord. *Obsoles.* — **spinal nerves**, *Anat. & Zoöl.*, the pairs of nerves which leave the spinal cord and, passing out by the intervertebral foramina, supply the muscles and skin of the trunk and limbs and connect with the nerves of the sympathetic system. In man there are normally 31 pairs (distinguished as *cervical*, *dorsal*, etc., according to their location), each nerve arising from the cord, as in other craniate vertebrates, by two short roots, a *ventral* (*anterior* in man), which is exclusively motor, and a *dorsal* (*posterior* in man), which bears a ganglion (*spinal ganglion*) close to the cord, and is afferent in function. They unite just beyond the ganglion to form a nerve of mixed function, which, after passing out through the foramen, divides in an anterior and a posterior division (both mixed nerves) to supply the dorsal and ventral regions.

spir'it (spĭr'ĭt), *n.* [OF. *espirit, esperit*, F. *esprit*, L. *spiritus*, fr. *spirare* to breathe, to blow. Cf. CONSPIRE, EXPIRE, ESPRIT, SPRITE.] **1.** The breath of life ; life, or the life principle, conceived as a kind of breath or vapor animating the body, or, in man, mediating between body and soul. The Galenic notion, accepted in the physiology of the Middle Ages, was that the spirit in the body existed in three kinds or degrees: (1) The **natural spirit**, a vapor rising from the blood and having its seat in the liver, was considered the principle of the "natural" functions of nutrition, growth, and generation. (2) The **vital spirit**, transformed from the natural spirit, in the heart, by mixture with the air of respiration, had the "vital" functions, conveying heat and life through the arteries to the whole body. (3) The **animal spirit**, converted in the brain from the vital spirit, included the rational principle, and had the "animal" functions of distributing the power of motion and feeling through the nerves. See ANIMAL, *a.*, 1.

2. The life principle viewed as the "breath" or gift of deity ; hence, the agent of vital and conscious functions in man ; the soul. *Spirit* (Heb. *nephesh*, usually translated "soul" in the Bible, Gr. *πνεῦμα*, Lat. *spiritus*) and *soul* are used sometimes as synonyms, sometimes as naming different elements in man's immaterial nature. In former use, *spirit* often denoted (as in def. 1) the vital principle of the body, as something inferior to *soul*. In current use *spirit* denotes a disembodied soul or (as in def. 5) an immaterial being which never had a body. Thus we speak of "*spirits* of the dead," "*spirit* return," the "land" or "realm of *spirits.*" See SOUL, 1, GHOST, 3.

I am thy father's *spirit ;*
Doomed for a certain time to walk the night. *Shak.*

Then shall the dust return to the earth as it was, and the *spirit* shall return unto God who gave it. *Eccl.* xii. 7.

Spirit is a substance wherein thinking, knowing, doubting, and a power of moving, do subsist. *Locke.*

3. [*often cap.*] In the abstract, life or consciousness viewed as an independent type of existence ; as, idealists maintain that the essential nature of the universe is *spirit*, pantheists that *spirit* pervades the universe. In this sense *spirit* denotes a quality or being similar to man's psychical or vital nature, conceived as a characteristic of nature or of deity. Thus, in Hebrew, *ruakh*, usually translated "spirit" in the Bible, denotes the divine breath independent of as well as in the body, and *nephesh*, "soul, spirit," denotes only the embodied breath. *Spirit* is also used to translate such terms (often rendered *mind*) as the Greek *νοῦς* (see NOUS, 1), Latin *mens*, German *Geist*, esp. in connection with idealistic theories. See IDEALISM, 1.

4. [*cap.*] A part of the divine nature ; the Holy Spirit.

sponge (spŭnj), *n.* [OF. *esponge*, F. *éponge*, L. *spongia*, Gr. σπογγιά, σπογγος. Cf. FUNGUS, SPUNK.] **1.** The elastic porous mass of interlacing horny fibers which forms the internal skeleton of certain marine animals of low organization belonging to the phylum Porifera, esp. those of *Euspongia*, *Hippospongia*, *Spongia*, and allies of warm or tropical seas. Sponges have great power of absorbing water, becoming soft when wet without losing their toughness. Also, the entire animal producing this skeleton, or any allied member of the phylum Porifera. The sponges are a large group, mostly marine, but a few inhabit fresh water. Except in the larval stage they are permanently attached, growing in a plantlike fashion into masses which vary much in size, shape, color, and consistency in the different members of the group. Their classification is usually based on the material of the skeleton, which may be entirely horny (composed, however, not of true horn, but of *spongin*), as in the commercial sponges, but generally the spongin is supplemented or replaced by siliceous spicules. Others have a calcareous skeleton, while in a few a skeleton is wanting. During life the interstices of the skeleton are filled with cells and pierced with a system of canals and small cavities opening on the surface by numerous incurrent orifices or pores, and one or many larger excurrent orifices (*oscula*). A current of water bearing with it the food (minute organisms, particles of organic matter, etc.) is maintained by collared, flagellated cells lining the cavities or canals. Reproduction occurs asexually in several ways, and sexually by means of egg and sperm cells which form a free-swimming larva.

Syn. — SPONTANEOUS, VOLUNTARY, AUTOMATIC. James*). That which is AUTOMATIC (like that which is *spontaneous*) is self-acting ; but *automatic* (unlike *spontaneous*) implies an activity which is merely mechanical ; as, "thoughts and phrases that rise *automatically* when the mind has prepared itself to receive them" (*Galton*) ; "An *automatic* action that fulfills a forgotten intention" (*G. Eliot*).

spo-ran'gi-um (-ŭm), *n.*; *L. pl.* -GIA (-ă). [NL.; Gr. σπόρος a sowing, seed + ἀγγεῖον a receptacle.] *Bot.* A spore case; specif., the sac or receptacle within which asexual spores are produced. In bacteria and certain algæ and fungi the sporangium is often a single cell (mother cell) giving rise endogenously to one or a few spores. In bryophytes there are no true sporangia (see SPOROGONIUM, THECA). In ferns and their allies the sporangia are more complex, and contain numerous spores developed from a primitive spore(archesporium)and nourished by a special layer of cells (tapetum). Discharge of the spores is aided by the elastic annulus (which see). In seed plants and heterosporous ferns the sporangia are of two kinds. See MICROSPORANGIUM, MEGASPORANGIUM, also FERN, *Illust.*; cf. GAMETANGIUM, GONIDANGIUM.
spore (spōr; 201), *n.* [Gr. σπορά or σπόρος a sowing, seed, fr. σπείρειν to sow. Cf. SPERM.] *Biol.* Any of various small or minute primitive reproductive bodies, typically unicellular, produced by plants (orig. one of the dustlike asexual reproductive bodies of fungi, ferns, etc.) and some protozoans, developed either asexually or through the union of two sex cells or gametes (which see). It was formerly supposed that the spores originally so called were analogous to the seeds of the higher plants; but it is now known that morphologically a spore is a nucleated mass of protoplasm with or without a cell wall, sometimes motile by means of flagella (see ZOÖSPORE), and capable of growth into a new individual either independently (asexual spore) or through union with another similar or dissimilar spore (sexual spore). A seed is a complex structure containing a resting embryo which has developed from the union of two sexual spores. See SEED, 1 **a**, ZYGOTE. In algæ and fungi the many types of asexual spores are distinguished by special names, as *ascospore*, *tetraspore*, *basidiospore*, *carpospore*, etc. In many pteridophytes and all seed plants the asexual spores are of two kinds, microspores and megaspores (see these terms). In protozoans the process of spore formation is an asexual one, and typically consists in the division of the cell contents (often after encystment of the cell) into many minute cells (spores) which are afterward liberated to swim away or become scattered. Less often the cell forms but one spore. Both in plants and animals spore formation often provides the organism with a means of surviving unfavorable seasons or extremes of temperature, the spores then being surrounded with a tough investing wall and possessing great tenacity of life. This is the case with the spores of many bacteria, and often greatly increases the difficulty of sterilization.
